# Introduce to Canny Edge Detection

- Canny Edge Detection is a technique used in image processing to detect edges, which are regions of rapid intensity changes in the image.
- Proposed by John Canny in 1986.
- Three main steps:
  - ◆ 1. Finding the gradient :
    - Magnitude
    - Direction
  - ◆ 2. Non-maximum suppression
  - ◆ 3. Hysteresis thresholding

## □ Layer0:Finding the gradient direction: $\arctan(G_y/G_x)$

- ◆ Fixed point division : 13-bit integer + 16-bit fraction
  - ◆  $G_y$  should left-shifted 16-bit for fractional part.
  - ◆  $(G_y \ll 16) / G_x = \text{temp\_result}$ .
  - ◆  $\text{temp\_result}$  is a 29-bit fixed-point number comprising a 13-bit integer part and a 16-bit fractional part.
- ◆ The angle is rounded to one of four angles :  $0^\circ$  ,  $45^\circ$  ,  $90^\circ$  ,  $135^\circ$  :
  - ◆  $\text{temp\_result} < 29'h00006A09 \ || \ \text{temp\_result} > 29'h1FFF95F7$  maps to  $0^\circ$ .
  - ◆  $\text{temp\_result} > 29'h00006A09 \ \&\& \ \text{temp\_result} < 29'h00026A09$  maps to  $45^\circ$ .
  - ◆  $\text{temp\_result} > 29'h00026A09 \ || \ \text{temp\_result} < 29'h1FFD95F7$  maps to  $90^\circ$ .
  - ◆  $\text{temp\_result} < 29'h1FFF95F7 \ \&\& \ \text{temp\_result} > 29'h1FFD95F7$  maps to  $135^\circ$ .

**NOTE : If  $G_x=0$ , it maps to  $90^\circ$**
